PRIORITY DOCUMENT
SUBMITTED OR TRANSMITTED IN
COMPLIANCE WITH
RULE 17.1(a) OR (b)

I, the undersigned, being an officer duly authorised in accordance with Section 74(1) and (4) of the Deregulation & Contracting Out Act 1994, to sign and issue certificates on behalf of the Comptroller-General, hereby certify that annexed hereto is a true copy of the documents as originally filed in connection with the patent application identified therein.

I also certify that by virtue of an assignment registered under the Patents Act 1977, the application is now proceeding in the name as substituted.

In accordance with the Patents (Companies Re-registration) Rules 1982, if a company named in this certificate and any accompanying documents has re-registered under the Companies Act 1980 with the same name as that with which it was registered immediately before re-registration save for the substitution as, or inclusion as, the last part of the name of the words "public limited company" or their equivalents in Welsh, references to the name of the company in this certificate and any accompanying documents shall be treated as references to the name with which it is so re-registered.

In accordance with the rules, the words "public limited company" may be replaced by p.l.c., plc, P.L.C. or PLC.

Re-registration under the Companies Act does not constitute a new legal entity but merely subjects the company to certain additional company law rules.

Signed

Andrew Gorse

Warning

After an application for a patent has been filed, the Comptroller of the Patent Office will consider whether publication or communication of the invention should be prohibited or restricted under Section 22 of the Patents Act 1977. You will be informed if it is necessary to prohibit or restrict your invention in this way. Furthermore, if you live in the United Kingdom, Section 23 of the Patents Act 1977 stops you from applying for a patent abroad without first getting written permission from the Patent Office unless an application has been filed at least 6 weeks beforehand in the United Kingdom for a patent for the same invention and either no direction prohibiting publication or communication has been issued, or any such direction has been revoked.

Notes

- a) If you need help to fill in this form or you have any questions, please contact the Patent Office on 0645 500505
- b) Write your answers in capital letters using black ink or you may type them.
- c) If there is not enough space for all the relevant details on any part of this form, please continue on a separate sheet of paper and write "see continuation sheet" in the relevant part(s). Any continuation sheet should be attached to this form.
- d) If you answered 'Yes' Patents Form 7/77 will need to be filed.
- e) Once you have filled in the form you must remember to sign and date it.
- f) For details of the fee and ways to pay please contact the Patent Office.

Catalyst bed combination

This invention relates to catalyst bed combinations and in particular to copper catalysts and guard beds therefor.

5 Copper catalysts are often employed for reactions involving hydrogen, for example simple hydrogenation reactions, e.g. the hydrogenation of aldehydes to alcohols, for methanol synthesis (where carbon oxides are reacted with hydrogen), methanol decomposition (where methanol, often in admixture with steam, is decomposed to form hydrogen and carbon oxides) and the shift reaction (where carbon monoxide is reacted with steam to produce hydrogen and
10 carbon dioxide) and the reverse shift reaction. Often, in order to obtain the optimum activity and stability of the catalyst, the catalyst is made with the copper in a highly dispersed form, for example by precipitation of a copper compound in the presence of, or together with, one or more support materials, especially zinc, magnesium, chromium and/or aluminium compounds. Following such precipitation, the composition is heated to convert the copper compounds, and,
15 if necessary also support materials, to the corresponding oxides. Prior to use for the desired reaction, the copper oxide is reduced to metallic copper. Particularly suitable catalysts for the above reactions are copper/zinc oxide/alumina and copper/zinc oxide/chromia compositions. In some cases part of the zinc may be replaced by magnesium and/or part of the alumina or chromia may be replaced by ceria or a rare earth such as lanthana.

20

The copper catalysts are readily de-activated by the presence of halide compounds and in particular chlorine compounds, such as hydrogen chloride, in the process gas undergoing the reaction. Traces of such chlorine compounds may arise from contaminants in the materials, for example hydrocarbon feedstock, steam, or air employed to make the process gas. Such
25 chlorine compounds react with the active copper, forming copper chloride. Since copper chloride is relatively low melting, at the temperatures at which the catalysts are commonly employed, e.g. 150-300°C, the copper is mobilised and tends to aggregate resulting in a loss of dispersion of the copper and consequent loss of activity of the catalyst. Also where zinc and/or magnesium oxide is a component of the catalyst, likewise the corresponding chlorides may be
30 formed, and these likewise are liable to be mobilised resulting in loss of the stabilising effect of the zinc or magnesium oxides, again with the consequent loss of dispersion and activity of the copper.

It has been proposed in our co-pending PCT application WO 01/17674 to employ a guard bed
35 upstream of the copper catalyst wherein the guard bed is a particulate composition containing a lead compound and a support therefor. That application discloses that the guard bed particles

may be made by impregnating particles of the support with a solution of a suitable lead salt, for example lead nitrate, by precipitating an appropriate lead compound in the presence of particles of the support material, or by co-precipitating a lead compound and the support, or a precursor to the support. The preferred lead compound was lead nitrate. However, there is a risk when using lead nitrate that, in the event of a plant upset, water may condense on the guard bed and leach the lead nitrate from the support and wash it on to the downstream copper catalyst. Lead compounds tend to poison copper catalysts and so there is the risk that the activity of the copper catalysts may be diminished. For this reason it may be preferable to use a lead compound that is not soluble in water.

In the aforementioned PCT application WO 01/17674 a commercial lead oxide supported on alumina and containing 20.4% by weight of lead was found to be a poor guard bed material compared to other lead compounds tested, providing activity only marginally better than alumina granules.

We have found that shaped units suitable for use as guard beds can be made simply from finely divided lead oxide particles and particles of a support material.

Accordingly the present invention provides a catalyst bed combination comprising a bed of a particulate copper-containing catalyst and, upstream of the catalyst bed, a guard bed of shaped units formed from lead oxide particles and a particulate support material.

By "lead oxide" we mean oxidic lead compounds including partially hydrated lead oxides. Such compounds include PbO , Pb_3O_4 and PbO_2 . Preferably the lead oxide is PbO . Particularly the lead oxide particles have an average (by weight) particle size below $50\text{ }\mu\text{m}$, more particularly $25\text{ }\mu\text{m}$, and preferably substantially all the particles have a size below $120\text{ }\mu\text{m}$. The guard bed is in the form of shaped units: these preferably have maximum and minimum dimensions in the range 1.5 to 20 mm, particularly 3 to 6 mm. The aspect ratio of the shaped units, i.e. the ratio of the maximum to minimum dimensions, is preferably less than 2.

The shaped units may be of regular shape, e.g. spheres, cylinders etc. and may be made by a "dry" technique wherein a powder composition comprising particulate lead oxide and particulate support material is compacted to the desired shape, in e.g. a pelleting machine, or a "wet" method wherein the powder composition is mixed with a suitable liquid to form a paste which is then extruded to the desired cross section and the extrudate is cut or broken into units of the requisite length. A granulation method may alternatively be employed wherein the powder

composition is mixed with a small amount of liquid, often water, insufficient to give a paste, and the resulting damp mixture granulated or pelletised by means of a pellet mill, for example of the type used for pelleting animal feedstuffs, wherein the mixture to be pelleted is charged to a rotating perforate cylinder through the perforations of which the mixture is forced by a bar or roller within the cylinder. The resulting extruded mixture is cut from the surface of the rotating cylinder by a doctor knife positioned to give pellets of the desired length. Alternatively, granulated materials may be used as the feed for a pelleting machine. Depending upon the moisture content, granulated materials may or may not need to be dried before use. Furthermore it may be desirable to calcine the shaped units. By the term "calcine" we mean heating in air to temperatures above 200°C.

The shaped units are formed from a mixture of the lead oxide particles and particles of a support material. By the term "support material" we mean finely divided support particles of an inert material. Suitable inert materials include alumina, a hydrated alumina, chromia, zirconia, titania, or, less preferably, silica. Alumina, or hydrated alumina are the preferred support materials. Most preferably, the support materials are hydrated aluminas having an average by weight particle size below 100 µm, more particularly below 50 µm, and preferably substantially all the particles have a size below 200 µm.

Whichever shaping method is used to form the shaped units, a processing aid such as a lubricant and/or a binder is preferably incorporated into the powder composition. Lubricants, which are generally employed when a "dry" processing route such as pelleting is used, include graphite, fatty acids and salts thereof such as stearates. A preferred lubricant is graphite. Binders that may be used may be inorganic, for example a clay, e.g. attapulgite, bentonite, sepiolite or colloidal magnesium aluminium silicate, or a cement, e.g. a calcium aluminate cement, or organic, e.g. a soluble carbohydrate such as starch, alginate or xanthan gum; a cellulose ether, e.g. hydroxy methyl cellulose; a protein; a polyvinyl alcohol, ester, acetal, or ether or mixed derivative e.g. a partially hydrolysed polyvinyl acetate; a polyalkylene oxide; a polyacrylate or methacrylate; or polyacrylamide or polymethacrylamide. Organic binders, if used, are preferred.

The amount of processing aid employed is generally 0.5 to 10%, particularly 1 to 5%, by weight, based upon the combined weights of the lead compound, support and processing aid.

Preferred compositions, containing a processing aid and a support, have a lead content of 5 to 75%, particularly 10 to 60%, by weight of lead (expressed as metal) and based upon the combined weights of the lead compound, support, and lubricant and/or binder.

- 5 An advantage of using shaped units comprising particulate lead oxide, support material and lubricant is that the shaped units need not be dried or calcined before use. However, if an organic binder is used, then irrespective of whether a wet or dry shaping method is employed, the shaped units are preferably calcined in air to burn out the binder. An advantage of using lead oxide rather than other lead compounds such as lead carbonate or basic lead carbonate is
10 its higher thermal stability that allows higher temperatures to be used to burn out the binder. Preferably temperatures greater than 200°C and more preferably greater than 400°C may be used.

- The guard bed and the catalyst bed are used as fixed beds and may be in the same vessel or
15 in different vessels, with the guard bed upstream of the catalyst bed. Preferably the process gas flows down through the catalyst bed: thus where the guard and catalyst beds are in the same vessel, the guard bed may be a layer of the guard bed particles on top of the catalyst bed particles. If desired there may be a layer of an inert material between the guard bed and the catalyst bed to facilitate replenishment of the guard bed without disturbing the catalyst bed.

- 20 Therefore according to a further aspect of the invention we provide a process for performing a catalytic reaction using a bed of a copper-containing catalyst, comprising passing a process gas through a guard bed of shaped units formed from particles of lead oxide and a particulate support material and then passing said process gas through the bed of copper-containing
25 catalyst.

- The invention is of particular utility in relation to the shift reaction. In this process a process gas stream containing carbon monoxide and steam, and often other components such as hydrogen, carbon dioxide, methane, and/or nitrogen, is passed through a bed of the copper-containing
30 catalyst, especially a copper/zinc oxide/alumina or copper/zinc oxide/chromia catalyst in which some of the zinc oxide may be replaced by magnesia and/or some of the alumina and/or chromia may be replaced by a rare earth, at a temperature in the range 150 to 300°C, especially at an inlet temperature in the range 150 to 250°C. The process gas preferably contains 1 to 4% by volume of carbon monoxide, and at least one mole of steam per mole of
35 carbon monoxide. Preferably the process gas contains 20 to 50% by volume of steam.

Typically the process is operated at a wet gas space velocity in the range 2000 to 5000 h⁻¹, and at pressures ranging from atmospheric to 50 bar abs.

5 In addition to absorbing chloride, it will be appreciated that the lead species will also absorb sulphur compounds and so the bed will also act as a sulphur guard bed.

The invention is illustrated by the following examples in which various guard beds were tested by charging 0.50 g (about 0.4 ml) of particles of a copper oxide/zinc oxide/alumina low temperature shift catalyst precursor containing about 50% by weight of copper oxide and
10 having a particle size in the range 0.6 – 1.0 mm to a microreactor with 0.25 g (about 0.1 ml) of particles of fused alumina of particle size 0.6 – 1.0 mm disposed as a layer on top of the shift catalyst precursor and 0.2 ml (about 0.36 g) of the guard material particles of particle size 0.6 – 1.0 mm on top of the fused alumina particles to give a total catalyst bed of volume of about 0.70 ml.

15 The copper oxide in the catalyst precursor was reduced to metallic copper by passing a stream of nitrogen containing 2% by volume of hydrogen down through the microreactor at a pressure of about 28 bar abs. at a flow rate of 15 litres/hour (at NTP) while the microreactor was heated from ambient temperature to 220°C and held at this temperature for 95 minutes to give a total
20 reduction time of 3.5 hours.

The catalyst activity for the water gas shift reaction was determined by passing 50 litres/hour (at NTP) of a gas mixture comprising 1 part by volume of steam to 2 parts by volume of a gas of volume composition H₂ 55%, CO₂ 15%, CO 5%, and N₂ 25% through the microreactor at a
25 temperature of 220°C and a pressure of about 28 bar abs.

To simulate chloride contamination, after the gas mixture had been passed through the catalyst bed for about 6 hours, HCl was added to the gas mixture to give an HCl concentration in the wet gas of 1 ppm by volume. Under these fixed test conditions, the variation of CO conversion
30 with time on line was measured using in-line infra-red detection. A decrease in CO conversion with time is indicative of loss of activity of the catalyst.

Example 1

35 Samples of chloride absorbent were made from lead oxide (PbO) and hydrated alumina powders. The lead oxide powder of Example 1(a) had a weight average particle size of 13.6 µm with essentially all of the particles having a size in the range 6.3 to 29.4 µm. The lead

oxide powder of Example 1(b) had a weight average particle size of 8.5 μm with essentially all of the particles having a size in the range 3.6 to 19.5 μm . The alumina trihydrate ($\text{Al}(\text{OH})_3$) powder had a BET surface area of 0.5 m^2/g and a weight average particle size of 21 μm with essentially all of the particles having a size in the range 5.1 to 54.3 μm . The Boehmite ($\text{AlO}(\text{OH})$) powder had a BET surface area of 228 m^2/g and a weight average particle size of 31.2 μm with essentially all of the particles having a size in the range 5.8 to 71.2 μm .

- (a) 60 g of alumina trihydrate powder was mixed for 5 min with 40 g of the lead oxide powder and 2 g of graphite as a lubricant and the mixture formed into squat cylindrical pellets of 25 mm diameter and 10-20 mm height using a pelleting machine at load of 20 tons. The pellets had a nominal lead content of 36.4% by weight and a density of about 3.5 g/ml.
- (b) 292 g of alumina trihydrate powder and 233 g of Boehmite powder were mixed for 5 min with 475 g of the lead oxide powder and 10 g of graphite as a lubricant and the mixture formed into squat cylindrical pellets of 62.5 mm diameter and 10-20 mm height using a pelleting machine at load of 20 tons. The pellets had a nominal lead content of 43.7% by weight and a density of about 3.5 g/ml.

Example 2

- The materials of Example 1 were tested as described above. Prior to use the pellets were broken down to particles of size 0.6 – 1 mm.

For purposes of comparison the following guard beds were also tested

- (a) a bed of the low-temperature shift catalyst,
- (b) a bed comprising a commercially available absorbent comprising lead oxide on alumina having a nominal lead content of about 20.5% by weight, and
- (c) a bed comprising lead oxide supported on alumina particles prepared by impregnation as follows; 303 g of gamma alumina particles of size 0.6 – 1.0 mm and having a BET surface area of 350 m^2/g was dipped in 800 ml of an aqueous solution of lead(II) nitrate at 60 to 70°C and of approximate concentration 55 g of lead(II) nitrate per 100 ml of solution. The material was removed from the solution after 30 minutes, drained, dried at 110°C for two hours and then calcined in an oven at 300°C for two hours. The above process was repeated using the calcined lead nitrate impregnated alumina prepared as above and a fresh quantity of the lead nitrate solution. After calcination at 300°C, the resultant material was re-dipped for a third time, again using a fresh amount of the lead nitrate solution. After calcination at 300°C for two hours the material had a lead content of 25.5% by weight. A portion of the material was then further calcined at 550°C for two hours to decompose lead

nitrate to lead oxide and yield a product with a lead content of 28.7% by weight. The increase in lead content indicates that lead oxide has formed.

Since the material of Example 2(b) had a significantly lower bulk density than the materials of Example 1, in this case a similar volume (about 0.2 ml) of absorbent was used but its weight was only about 0.19 g.

The % CO conversion was determined for a period of several days with measurements being taken at regular intervals. To assist comparison, the CO conversion measurements were plotted against time-on-line and a smooth curve drawn through the points for each sample. (The individual points showed little variance from the smooth curves). From these plots, the conversion every 24 hours was determined and the results are shown in the following Table wherein the % CO conversion figures have been rounded to the nearest integer.

Time on line (days)	CO Conversion (%)				
	Ex 1a	Ex 1b	Ex 2a	Ex 2b	Ex 2c
1	84	84	84	85	86
2	81	81	79	81	85
3	79	79	75	72	77
4	78	77	62	50	57
5	76	76	34	7	13
6	75	75	3	0	0
7	74	73	0	0	0
8	74	67	0	0	0
9	71	42	0	0	0
10	57	0	0	0	0

5 The results demonstrate that the shaped units comprising particles of lead oxide and a particulate support are superior to commercial supported PbO and a supported PbO-containing material prepared by impregnation.

Claims

1. A catalyst bed combination comprising a bed of a particulate copper-containing catalyst and, upstream of the catalyst bed, a guard bed of shaped units formed from lead oxide particles and a particulate support material.
2. A combination according to claim 1 wherein the support material is selected from alumina, hydrated alumina, chromia, zirconia, and titania.
3. A combination according to claim 1 or claim 2 wherein the shaped units are formed from a composition containing a processing aid.
4. A combination according to claim 3 wherein the shaped units are formed from a composition containing a processing aid and have a lead content of 5 to 75%, by weight of lead (expressed as metal) based upon the combined weights of the lead oxide, support material, and processing aid.
5. A combination according to claim 4 wherein the shaped units are formed from lead oxide, hydrated alumina and graphite and are not subjected to a calcination step.
6. A combination according to any one of claims 1 to 4 wherein the lead oxide used to form the shaped units has an average (by weight) particle size below 50 μm .
7. A combination according to any one of claims 1 to 6 wherein the shaped units have maximum and minimum dimensions in the range 1.5 to 20 mm.
8. A combination according to any one of claims 1 to 7 wherein the shaped units have an aspect ratio of less than 2.
9. A process for performing a catalytic reaction using a bed of a copper-containing catalyst, comprising passing a process gas through a guard bed of shaped units formed from particles of lead oxide and a particulate support material and then passing said process gas through the bed of copper-containing catalyst.

Abstract

A combination comprising a bed of a particulate copper-containing catalyst and, upstream of the catalyst bed, a guard bed in the form of shaped units formed from lead oxide particles and a particulate support material. The guard bed extends the life of the copper catalyst by absorbing halide contaminants in the process stream.
